

Introduction

The SPC58EC-DISP discovery+ board is a development board to evaluate and to develop applications with the microcontroller SPC58EC80E5 in eTQFP144 package.

The SPC58EC80E5 is a microcontroller targeting Body, Networking and Security applications.

This document describes the hardware architecture of the board and how it is possible to enable specific functions through the configuration of the jumpers.

1 SPC58EC-DISP discovery board

Figure 1. SPC58EC-DISP - top side

The several interfaces including Ethernet controller, CAN-FD, FlexRay, LIN and UART, ADC, and JTAG port make the SPC58EC-DISP an excellent tool to evaluate the microcontroller as well as to develop and then debug applications.

An integrated programmer debugger (supported PLS) allows debugging and programming the microcontroller. The same section allows enabling a USB Virtual COM port.

Dedicated connectors allow plugging shields Arduino UNO R3-compatible. This feature makes it simple to expand the board functionality adding a shield or board available on the market. All GPIOs and main signals are accessible by a 4x37 0.1" pin array.

2 Hardware overview

2.1 Power supply section

The input voltage level is 12V_{DC}, the output voltage is set to 5 V and 3.3 V.

Figure 2 and *Figure 3* show the buck converters used to generate 5 V and 3.3 V respectively.

Figure 4 shows a 3.3 V linear regulator; it is suitable to supply the ADC section.

Figure 2. 12 V - 5 V Buck converter

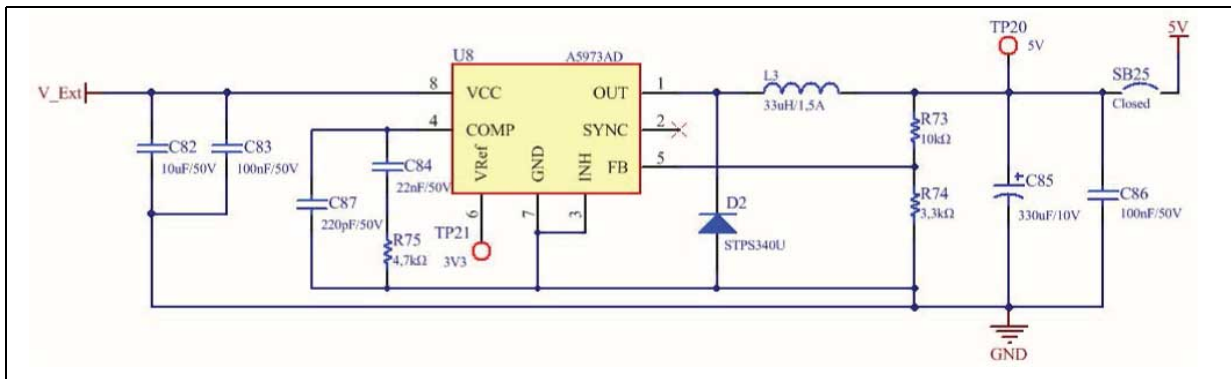

Figure 3. 3.3 V Buck converter

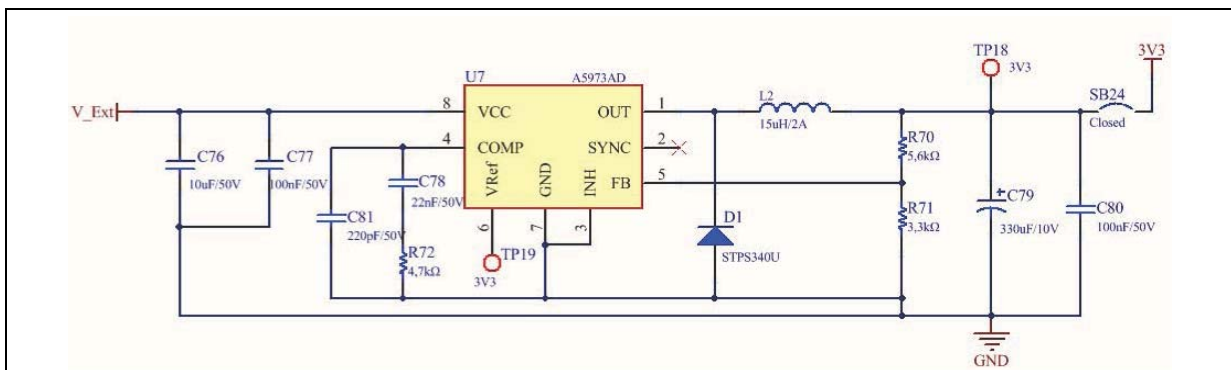

Figure 4. 3.3 V linear converter

2.2 Microcontroller power management

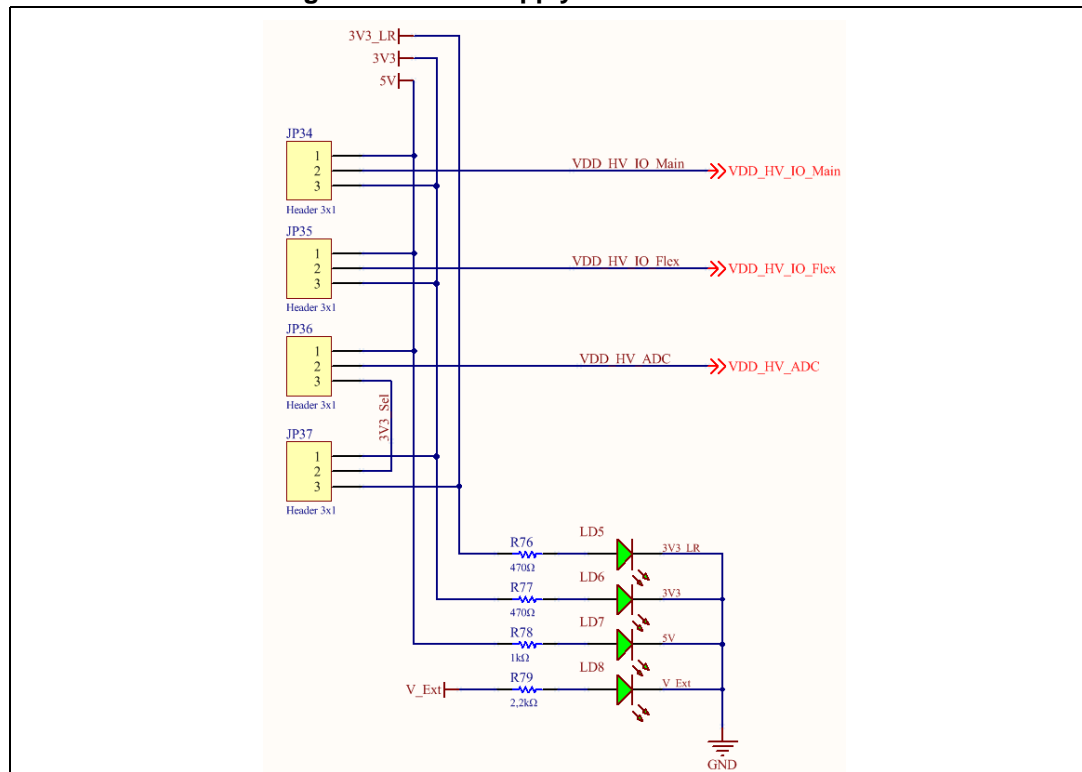

JP34 allows selecting the voltage level to supply VDD_HV_IO_main (5 V or 3.3 V); as well as JP35 sets the VDD_HV_IO_Flex level.

JP36 sets the VDD_HV_ADC supply level; JP37 sets the 3.3 V source (from linear or switching regulator).

These jumpers allow the evaluation of the current absorption.

The LEDs D5, D6, D7 and D8 provide a feedback about the status of the power supply section.

Figure 5. Power Supply Selector and LEDs

2.3 Integrated Programmer/Debugger

The integrated programmer/debugger allows the user to program the microcontroller, to build and to debug the software applications. The debugger works with the UDE PLS software.

The debugger serial number is a label applied on the PCB bottom side.

The integrated debugger SW is accessible via ST's free integrated development environment, SPC5Studio (www.st.com/spc5studio). To download the debugger software and to activate license refer to the PLS website.

The core of the debugger is a single chip USB to dual serial / parallel ports. A portion of the device manages the JTAG signals while the second part implements a UART

communication channel; the level shifters are necessary to balance the signals levels (3.3 V↔5 V).

The supply comes from PC through the USB cable and a dedicated 3.3 V linear regulator supplies this section.

The microcontroller can be programmed and debugged also by using external tools connected to a JTAG port (2x7 pin). The solder jumper from SB8 to SB14 allows disconnecting the JTAG signal from the integrated debugger^(a).

SPC58EC-DISP comes with the integrated programmer enabled (all solder jumpers from SB8 to SB14 are present).

2.4 Crystal oscillator and Reset

Figure 6 shows the external oscillator circuit; the frequency is 40MHz.

By setting SB2, SB3 (open) and SB3 (closed) it is possible to drive the EXTAL pin with an external clock.

Figure 6. Crystal oscillator

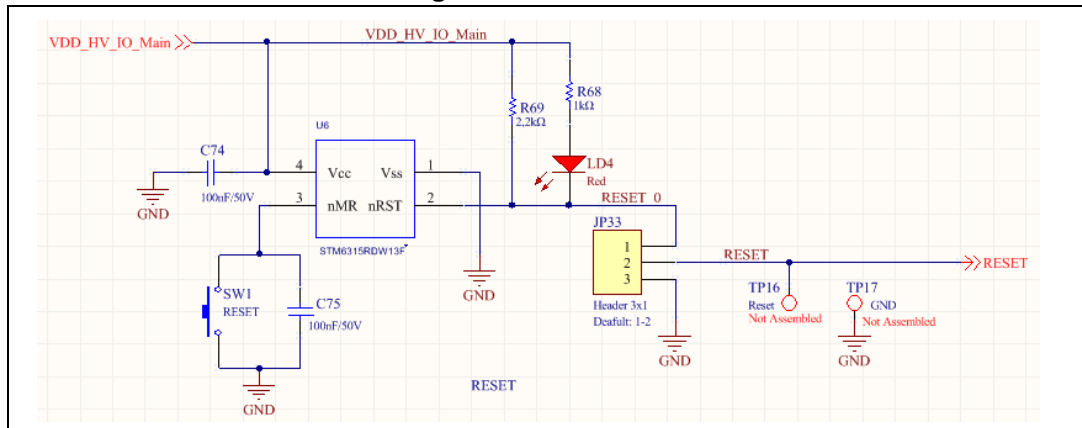

The reset circuit is the device STM6315.

The STM6315 (Figure 7) asserts a reset signal whenever the Vcc pin drops below 2.63 V and keep it asserted until the level of Vcc has risen above the threshold for a 210ms.

a. An external debugger must be used with the USB cable disconnected and under this working condition; the integrated debugger is not supplied. If the external programmer does not work properly, the jumpers SB8÷SB14 must be removed (open). It is suggested to perform some tests before removing the jumpers SB8÷SB14.

Figure 7. Reset circuit

The device generates a reset signal when the SW1 button is pressed.

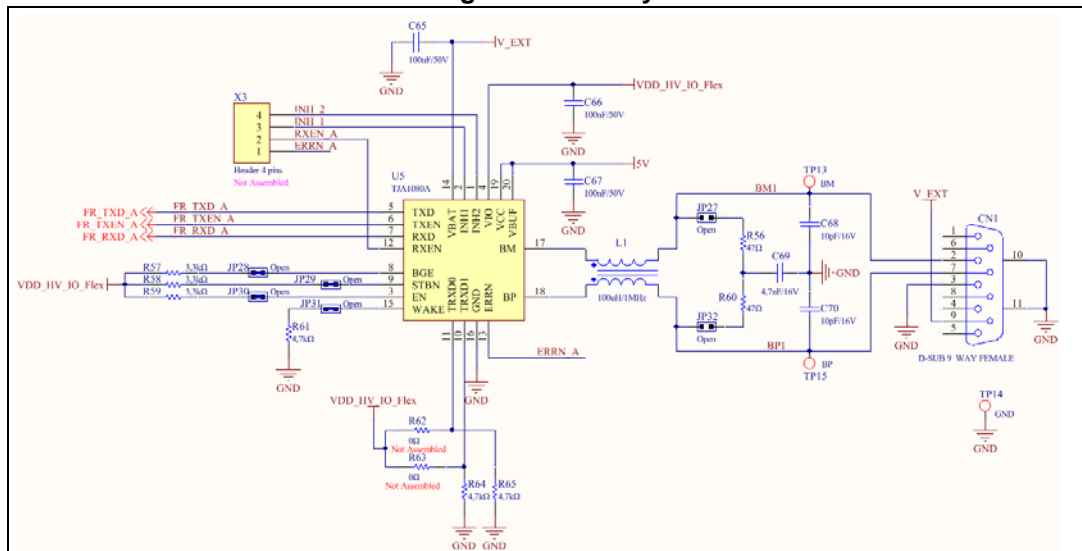

The reset output is an open drain pin and it must be pulled-up to VDD_CPU voltage level (R69). The LD4 provides a feedback when the reset pulse is generated.

2.5 FlexRay

[Figure 8](#) shows the FlexRay section (transceiver + DB9 connector).

The jumpers JP27 and JP32 connect the load terminations (47Ω). The jumpers from JP28 to JP31 allow configuring the transceiver.

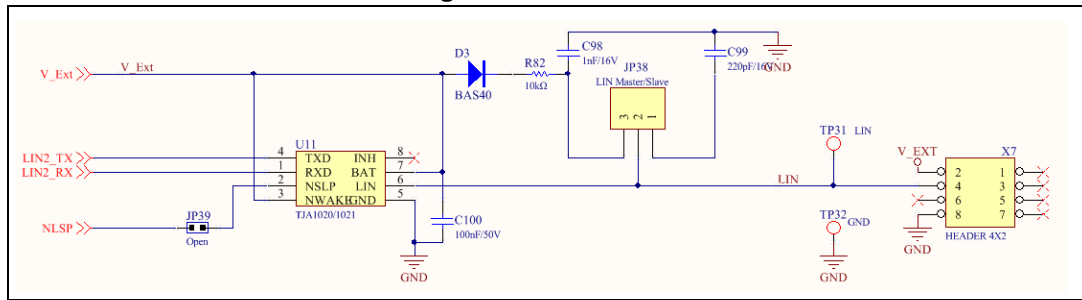

Figure 8. FlexRay

2.6 LIN and RS232

[Figure 9](#) shows the LIN circuit; JP38 allows setting Master/Slave mode.

Figure 9. LIN section

Two serial communication channels are available; U10 is a dual RS232 driver and receiver.

2.7 CAN & ISO CAN-FD

Two CAN channels are available, both are based on a fast transceiver; the implemented solution is compatible with CAN-FD operation standard.

The jumper JP2 allows the selection in normal or standby mode:

- No jumper: normal operation^(b)
- Jumper 2-3: device in standby mode (manual or fixed selection)
- Jumper 1-2: stand-by is driven by the microcontroller (dynamic configuration).
- Jumper JP1 enables the load termination.

2.8 Ethernet

Resistors R14, R15, R16 and R17 are the load termination.

The jumpers in P14 (2x10 male pins) enable the signals from the microcontroller to drive the transceiver (see [Table 2](#)).

Note: The transceiver supply voltage is 3.3 v; the microcontroller supply must be set consequently.

JP5 allows connecting the Ethernet transceiver to the microcontroller to implement RII or MII communication protocol.

JP5 allows the implementation of another feature: its pins allow plugging an addition board to evaluate the communication performance by using a different Ethernet physical layer.

R29 ÷ R32 are the load termination resistors.

Note: The level of the transceiver in/out pins is 3.3V then the microcontroller supply level must be set consequently.

2.9 User interface (pushbuttons, LEDs and trimmers)

In the board three LEDs and three push-buttons are present and they are suitable for user purposes ([Figure 11](#)).

b. In the transceiver an internal pull-up resistor is already present and R1 could be removed

Two trimmers allow the evaluation of the ADC performance (see [Figure 12](#)).

Figure 10. User Pushbutton and LEDs

Figure 11. User LEDs

2.10 Extended connectors (I/O Headers)

Most of the GPIOs and signals are accessible by the connector X9, a 4x37 male pin array allowing connection of additional boards and with the user HW application. [Table 1](#) and [Table 2](#) summarize the function and signal of each pin.

Table 1. X9 (part I) - Extended Connectors (I/O Headers)

X9 pin	Function / Port	X9 pin	Function / Port
A1	GND	B1	5V
